Greedy Algorithms

A greedy algorithm always makes the choice that looks best at this moment.

Practice problems:

1. Fractional knapsack

```
Function Fractional-Knapsack (W, v[n], w[n])

1. Order item-list by v<sub>i</sub>/w<sub>i</sub> descending

2. while w > 0 and as long as there are items remaining

3. pick item with maximum v<sub>i</sub>/w<sub>i</sub>

4. x<sub>i</sub> ← min (1, w/w<sub>i</sub>)

5. remove item i from list

6. w ← w - x<sub>i</sub>w<sub>i</sub>

w: the amount of space remaining in the knapsack (initially w = W)
```

2. Activity Selection Problem

Greedy algorithms for this problem:

- Sort by start time
- Sort by finish time (this one gives the optimal answer)
- Sort by interval

The following two pseudo codes assume that the activities are sorted according to finish time.

Recursive version:

```
RECURSIVE-ACTIVITY-SELECTOR (s, f, k, n)

1 m = k + 1

2 while m \le n and s[m] < f[k] // find the first activity in S_k to finish

3 m = m + 1

4 if m \le n

5 return \{a_m\} \cup \text{RECURSIVE-ACTIVITY-SELECTOR}(s, f, m, n)

6 else return \emptyset
```

For-loop version:

```
GREEDY-ACTIVITY-SELECTOR (s, f)

1  n = s.length

2  A = \{a_1\}

3  k = 1

4  for m = 2 to n

5  if s[m] \ge f[k]

6  A = A \cup \{a_m\}

7  k = m

8 return A
```

Activity selection in different scenario: Version 1

Suppose you are a coder. You write code for money and charge each customer the same amount, \mathbf{M} , irrespective of how many hours it takes to write the code. Your customers have sent you \mathbf{n} coding requests for tomorrow. Each coding request contains the customer id (c_i) , the start time (s_i) and the duration (d_i) of the coding task. Write a code to maximize your income tomorrow. Note that you can only write code for one customer at a time.

Sample input	Sample output
M	
N	
c_1, s_1, d_1	
c_n , s_n , d_n	
10	Profit: 3x10=30
4	Chosen tasks:
a 2 8	b
b 3 4	С
d 8 1	d
c 7 1	

Activity selection in different scenario: Version 2

Note that you need **X** hour break between two code writing tasks.

Sample input	Sample output
M, X	
N	
c_1, s_1, d_1	
c_n, s_n, d_n	
10 1	Profit: 2x10=30
4	Chosen tasks:
a 2 8	b
b 3 4	d
d81	
c71	

3. Maximize your payment

Suppose you are temporarily working as a photoshop editor. You work **10 hours a day** from 12:00 PM to 10 PM. Each of your customers sends you a task request for the next day. The task request contains the payment (p_i), the duration (d_i), and the deadline (dl_i). You must complete a task within the given deadline to get the payment. **Write the following greedy algorithm to maximize your payment.** Note that you can move on to a new task leaving the current task partially complete, and then come back to it later.

Algorithm:

- 1. Sort the tasks by descending order of payment per hour.
- 2. Choose the task with the maximum *payment per hour* and do it in the last possible hours. Make that hour occupied.
- 3. Choose the next maximum paid (*payment per hour*) task, find the last possible time that is not occupied, do it at that time and make that hour occupied. If no such time exists, you cannot do this task.
- 4. Move to the next maximum profitable task (based on payment per hour) and repeat step 3.

Sample Input			Sample Output	
				c, a
Customer	Last time (PM)	Time needed (hour)	Payment (Tk)	6000
а	4	2	2000	
b	1	1	1000	
С	1	1	4000	
d	2	2	3000	
<u> </u>			c, a, e	
Customer	Last time (PM)	Time needed (hour)	Payment (Tk)	1420
а	2	1	1000	
b	1	1	190	
С	2	1	270	
d	1	1	250	
е	3	1	150	

4. Greedy Coin Change

Consider the problem of making change for **N** cents using the fewest number of coins. Assume that each coin's value is an integer. Write a greedy algorithm to make change consisting of quarters (25 cents), dimes (10 cents), nickels (5 cents), and pennies (1 cent).

Sample input	Sample output
N	
173	25 cents 6
	10 cents 2
	1 cents 3
	Total 11 coins

Consider the problem of making change for **N** cents using the fewest number of coins. Assume that each coin's value is an integer. Write a greedy algorithm to make change consisting of coins $c_1, c_2, ..., c_d$.

Sample input	Sample output
N	
d	
c_1, c_2, \dots, c_d	
173	25 cents 6
10 1 25 5	10 cents 2
	1 cents 3
	Total 11 coins

5. Determine the smallest set of unit-length closed intervals

Given a set $x1 \le x2 \le \cdots \le xn$ of points on the real line, give an algorithm to determine the smallest set of unit-length closed intervals that contains all of the points. A closed interval includes both its endpoints; for example, the interval [1: 25; 2: 25] includes all xi such that $1.25 \le xi \le 2.25$.

6. Huffman Encoding

```
HUFFMAN(C)

1 n = |C|

2 Q = C

3 for i = 1 to n - 1

4 allocate a new node z

5 z.left = x = EXTRACT-MIN(Q)

6 z.right = y = EXTRACT-MIN(Q)

7 z.freq = x.freq + y.freq

8 INSERT(Q, z)

9 return EXTRACT-MIN(Q) // return the root of the tree
```

Huffman Decoding
